Course name: Network Optimization

Course no: 42115

## Critical path problem

**Answer 1** We insert a new node  $s$  and connect it to the first two activities  $A, B$ . We insert a new node  $t$  and connect it to the last two activities  $H, I$ . This gives the following graph (duration of activities is indicated with black on the nodes):

Now we solve the problem

- *Forward procedure:* Starting at time zero, calculate the earliest time  $U_j$  each job  $j$  can be started  $U_j = \max_{(i,j) \in E} \{U_i + p_i\}$ . (marked with blue, above)
- *Makespan:*  $T = U_t$ .
- *Backward procedure:* Starting at time equal to the makespan, calculate the latest time  $V_j$  each job  $j$  can be started so that this makespan is realized.  $V_i = \min_{(i,j) \in E} \{V_j - p_i\}$  (marked with red, above)

The critical path schedule solution for this project is given below:

| Activity | Duration | Earliest start time $U_j$ | Latest start time $V_j$ |
|----------|----------|---------------------------|-------------------------|
| s        | 0        | 0                         | 0                       |
| A        | 4        | 0                         | 0                       |
| B        | 3        | 0                         | 9                       |
| C        | 8        | 4                         | 4                       |
| D        | 7        | 4                         | 15                      |
| E        | 9        | 12                        | 13                      |
| F        | 12       | 12                        | 12                      |
| G        | 2        | 21                        | 22                      |
| H        | 5        | 21                        | 25                      |
| I        | 6        | 24                        | 24                      |
| t        | 0        | 30                        | 30                      |

The makespan is  $T = 30$ . ■

**Answer 2** The critical path is found for activities where earliest start time  $U_j$  is equal to the latest start time  $V_j$  in the above table. This means projects  $A, C, F, I$ . The critical path is marked with bold edges in the above graph. ■

## Fixed charge transportation problem

**Answer 3** We have the following possible patterns

|               | $S_1$ |    |    | $S_2$ |   | $S_3$ |    |   |
|---------------|-------|----|----|-------|---|-------|----|---|
| $T_1$         | 3     | 2  | 1  | 1     | 0 | 2     | 1  | 0 |
| $T_2$         | 0     | 1  | 2  | 0     | 1 | 0     | 1  | 2 |
| transp. cost  | 12    | 11 | 10 | 5     | 2 | 14    | 8  | 2 |
| fixed charges | 5     | 10 | 10 | 5     | 5 | 5     | 10 | 5 |
| sum of costs  | 17    | 21 | 20 | 10    | 7 | 19    | 18 | 7 |

This leads to the Dantzig-Wolfe decomposed model:

```

minimize
17p11+21p12+20p13+10p21+ 7p22+19p31+18p32+ 7p33
subject to
3p11+ 2p12+ 1p13+ 1p21+ 0p22+ 2p31+ 1p32+ 0p33 = 4    (u1)
0p11+ 1p12+ 2p13+ 0p21+ 1p22+ 0p31+ 1p32+ 2p33 = 2    (u2)

p11+  p12+  p13                                     = 1    (v1)
          p21+  p22                                   = 1    (v2)
                        p31+  p32+  p33                 = 1    (v3)

```

```

binary p11 p12 p13 p21 p22 p31 p32 p33
end

```

**Note:** In principle, one can add a pattern  $p_{14}$  for  $S_1$  transporting  $(0,3)$  but this pattern will never be used. However it does not make any harm. ■

**Answer 4** The greedy solution uses patterns  $p_{13} = (1,2), p_{21} = (1,0), p_{31} = (2,0)$ . ■

**Answer 5** Let  $a_{ip}$  be the coefficients in the two first lines of the pattern formulation, and  $b_{ip}$  be the coefficients in the last three lines. Reduced cost for pattern  $p$  is then calculated as

$$\bar{c}_p = c_p - \sum_i a_{pi} u_i - \sum_i b_{pi} v_i$$

where we have  $u_1 = 0, u_2 = 10, v_1 = 0, v_2 = 10, v_3 = 19$ . This gives the following reduced costs (we do not need to calculate reduced costs of paths which already are present in the master problem)

| pattern $p$ | $c_p$ | $\sum_i a_{pi} u_i$ | $\sum_i b_{pi} v_i$ | $\bar{c}_p$ |
|-------------|-------|---------------------|---------------------|-------------|
| $p_{11}$    | 17    | 0                   | 0                   | 17          |
| $p_{12}$    | 21    | 10                  | 0                   | 11          |
| $p_{22}$    | 7     | 10                  | 10                  | -13         |
| $p_{32}$    | 18    | 10                  | 19                  | -11         |
| $p_{33}$    | 7     | 20                  | 19                  | -32         |

Pattern  $p_{33}$  has the most negative reduced cost. Notice that in pattern  $p_{33}$  the sum  $\sum_i a_{pi}u_i = 20$  since we are sending two units. ■

## Maximum flow

**Answer 6** We use the paths:

| path   | capacity |
|--------|----------|
| sCDBt  | 4        |
| sCBt   | 3        |
| sADt   | 2        |
| sABCDt | 1        |

This results in the following solution (edge labels are: capacity/flow):

The maximum flow is 10.

**Alternative solution:** use path  $sABDt$  in the last iteration with capacity 1.

■

**Answer 7** A minimum cut is  $\{s, A, B, C, D\}$  and  $\{t\}$ . The capacity of the cut is  $7 + 3 = 10$ . This corresponds to the solution found above. ■

## Minimum cost flow problem

**Answer 8** In order to formulate the problem as a *minimum cost flow problem*, we introduce two nodes for each day. Node  $A_i$  represents the start of day  $i$ , and  $B_i$  represents the end of the day. If the demand of napkins at day  $i$  is  $d_i$ , then node  $A_i$  has a demand  $d_i$  and node  $B_i$  has demand  $-d_i$ .

At the end of day  $i$  we can wash napkins in two possible ways. At cost 3 they can be ready at the beginning of day  $i + 1$ , or at cost 1 they can be ready at day  $i + 2$ . This means that each node  $B_i$  is connected to node  $A_{i+1}$  at cost 3, and to node  $A_{i+2}$  at cost 1. The capacity of the edges is infinite.

We can also buy napkins every day at cost 8. We therefore introduce a source  $s$  representing buying new napkins. Every node  $A_i$  is connected with an edge from  $s$  at a cost of 8 with infinite capacity.

Finally, we need to get rid of all napkins not washed. This can e.g. be modeled by connecting node  $B_i$  to node  $B_{i+1}$  at cost 0, and from node  $B_5$  to node  $s$  at cost 0. The edge capacities are infinite.

This gives the following graph formulation:

All edge capacities are infinite.

**Alternative solution:** Add a terminal node  $t$  for all napkins not washed. Connect all  $B_i$  nodes to  $t$  at cost 0. Give  $s$  a demand of  $-\sum d_i = -1500$  and  $t$  a demand of  $\sum d_i = 1500$ . Finally, add an extra edge from  $s$  to  $t$  having cost 0. In this way a sufficient amount of new napkins is available at  $s$ , and when napkins are not used any more they disappear at  $t$ . Excess napkins which are not used in the catering are sent directly from  $s$  to  $t$  at cost 0. ■

## Arbitrage opportunity

|     | USD  | EUR  | DKK   | CHF  | GBP  |
|-----|------|------|-------|------|------|
| USD | 1.00 | .88  | 6.54  | .96  | .65  |
| EUR | 1.14 | 1.00 | 7.46  | 1.09 | .74  |
| DKK | .15  | .13  | 1.00  | .15  | .10  |
| CHF | 1.05 | .92  | 6.84  | 1.00 | .68  |
| GBP | 1.54 | 1.35 | 10.05 | 1.47 | 1.00 |

**Answer 9** The problem can be formulated by use of a complete directed graph, where each node corresponds to a currency, and edge weights correspond to the exchange rate. We are looking for a cycle where the product of the edges is larger than 1.00.

To solve this problem we first take the logarithm to the exchange rates, and then we multiply by -1 to change maximization to minimization. In this way the problem becomes to find a *negative cost cycle* in the graph. This can be done by use of *Bellman-Ford*.

**Note:** It is not possible to solve the above problem as a *shortest path problem* since if we have a negative cost cycle, the distances are not welldefined, and the algorithm may not terminate.

**Note:** It should not be necessary to add a source  $s$  and a sink  $t$  to the graph. Indeed, if all nodes (currencies) are connected to the source  $s$ , and also all nodes (currencies) are connected to the sink  $t$  then you may risk that you start with one currency and end up with a different currency! It is always easy to exchange e.g. GBP to DKK so that you get more units, but the overall value will not necessarily be better. ■

The following table illustrates the transformation. Each entry is the  $-\log(e_{ij})$  of the original exchange rate  $e_{ij}$ . Each currency will be a node, and the edge weights are given in the table.

|     | USD     | EUR     | DKK     | CHF     | GBP    |
|-----|---------|---------|---------|---------|--------|
| USD | 0       | 0,05558 | -0,8156 | 0,0177  | 0,1871 |
| EUR | -0,0569 | 0       | -0,8727 | -0,0374 | 0,1308 |
| DKK | 0,8239  | 0,886   | 0       | 0,8239  | 1      |
| CHF | -0,0212 | 0,0362  | -0,835  | 0       | 0,167  |
| GBP | -0,1875 | -0,1303 | -1,002  | -0,167  | 0      |

## Shortest path

**Answer 10** The following table states for each iteration which node is considered, and what the so far best distances are to each node. When a node has been considered, the distance is not changed any more.

| considered<br>node | distance |          |          |          |          |
|--------------------|----------|----------|----------|----------|----------|
|                    | $s$      | $A$      | $B$      | $C$      | $D$      |
| init               | 0        | $\infty$ | $\infty$ | $\infty$ | $\infty$ |
| $s$                |          | 10       |          | 5        |          |
| $C$                |          | 8        | 14       |          | 7        |
| $D$                |          |          | 13       |          |          |
| $A$                |          |          | 9        |          |          |
| $B$                |          |          |          |          |          |

The shortest path tree is marked with fat edges below (shortest distance marked with red):

■

## Multi-commodity Flow

**Answer 11** Every node  $v$  with a capacity  $c_v$  is split into two nodes  $v, v'$ . All ingoing edges are connected to  $v$  while all outgoing edges are connected to  $v'$ . A new edge  $(v, v')$  is added with capacity  $c_v$  and cost 0.

This gives us the following standard multi-commodity flow problem

■

**Answer 12** If all demands are to be transported unsplittable, we notice that commodity 1 can either use path  $ABC$  or path  $ABEC$ .

Due to the capacity constraints in nodes  $B$  and  $E$  commodity 1 and commodity 2 cannot pass through nodes  $B$  and  $E$  at the same time. Therefore, if commodity 1 chooses path  $ABEC$  it will not be possible to send commodity 2 through the network. We can therefore conclude that commodity 1 will use path  $ABC$ .

Now, commodity 2 can only use path  $DEF$  since no other paths have sufficient capacity.

This gives the solution: Commodity 1 use path  $ABC$  and commodity 2 use path  $DEF$ . The total cost is  $5 \cdot (2 + 8) + 10 \cdot (6 + 9) = 50 + 150 = 200$ . ■
